

Why do batteries vary in size and voltage?

Batteries vary both in size and voltage due to the chemical properties and contents within the cell. However, batteries of different sizes may have the same voltage. The reason for this phenomenon is that the standard cell potential does not depend on the size of a battery but rather on its internal content.

How do op amps work?

The Op Amps control the battery discharge current and voltage, functioning in the same manner as they do when the battery is being charged. The boost converter boosts the battery voltage to VDC, which is usually 12 V. Figure 2. Battery Test Equipment Typical Amplifier Configuration

How does a battery work?

The two electrodes are each submerged in an electrolyte, a compound that consists of ions. This electrolyte acts as a concentration gradient for both sides of the half reaction, facilitating the process of the electron transfer through the wire. This movement of electrons is what produces energy and is used to power the battery.

Which op amp is best for a high voltage battery?

Assuming the temperature rises from 25°C to 85°C and the battery voltage is 4 V, we can easily calculate the real world error from one of our low-offset and low offset drift Op Amps, the TLV07. a precision Op Amp similar to TLV07 is an ideal Op Amp to meet the system output current and voltage error requirements.

What is the relationship between current and voltage?

where I is the current, k is a constant of about 1.3, t is the time the battery can sustain the current, and Q_p is the capacity when discharged at a rate of 1 amp. There is a significant correlation between a cell's current and voltage. Current, as the name implies, is the flow of electrical charge.

How does temperature affect battery performance?

The rate of side reactions can be slowed by lowering temperature. Warmer temperatures can also lower the performance of the battery, by speeding up the side chemical reactions. Primary batteries become polarized with use. This is when hydrogen accumulates at the cathode, reducing the battery's effectiveness.

If my deduction is correct, you can increase the current by increasing the surface area of the plates and by increasing the conductivity of the medium (add salt and/or acid). If indeed you are harvesting Telluric earth currents you can increase currents by using plates with larger surface areas and putting them in parallel with

similar plates spread out east-west.

But the maximum collector current will be determined by supply voltage, 470ohm resistor, LED voltage drop and V_{cesat} . That is: $I_{c-max} = (5 - V_{led} - V_{cesat}) / 470$ Your max collector current can be about what you measured, abt 8mA. If you want 100mA collector current you should first set PS current limit above 100mA and reduce 470ohm resistor.

With energy, it isn't possible to get a free lunch. It's relatively easy to amplify a microampere signal up to milliamperes, but that's because the extra current comes from some type of power supply. This doesn't work when the signal you're trying to amplify is the power supply.. You might be able to use a transformer to trade current for voltage.
