

Are colloidal electrodes suitable for ultra-stable batteries?

Volume 27, Issue 11, 15 November 2024, 111229 Current solid- and liquid-state electrode materials with extreme physical states show inherent limitation in achieving the ultra-stable batteries. Herein, we present a colloidal electrode design with an intermediate physical state to integrate the advantages of both solid- and liquid-state materials.

What is a soft colloidal electrode material?

The soft, colloidal electrode material was realized through an inherent water competition effect between the $(\text{SO}_4)^{2-}$ species from the aqueous electrolyte and inherently water-soluble polyethylene glycol (PEG)/ZnI₂ from the cathode, forming an aqueous Zn||PEG/ZnI₂ colloid battery (Figure 1 A).

What is a colloidal electrode based on?

The colloidal electrode was designed based on the inherent water competition effect of $(\text{SO}_4)^{2-}$ from the aqueous electrolyte and inherently water-soluble polyethylene glycol (PEG)/ZnI₂ from the cathode.

Can colloidal synthesis be used in batteries of tin-based materials?

Colloidal synthesis is a powerful synthetic strategy and has been successfully applied for controllably synthesizing tin-based nanomaterials. In this feature article, we have focused on the developments from our group in colloidal synthesis and application in batteries of tin-based materials.

Why are colloidal electrodes better than solid-state electrodes?

Colloidal electrode materials offer competitive fixation properties for redox-active species compared to conventional solid-state electrodes, while preventing the particle cracking or pulverization observed in conventional solid-state electrode materials, such as inorganic and organic particles.

Can colloidal electrolyte stabilize cryogenic Zn metal battery?

Here, the authors design a "beyond aqueous" colloidal electrolyte with ultralow salt concentration and inherent low freezing point and investigate its colloidal behaviors and underlying mechanistic principles to stabilize cryogenic Zn metal battery.

In this context, we present colloidal Bi nanocrystals (NCs) as a model anode material for the exploration of cathode materials for rechargeable Mg-ion batteries. Bi NCs demonstrate a stable capacity of 325 mAh g⁻¹ over at least 150 cycles at a current density of 770 mA g⁻¹, which is among the most-stable performance of Mg-ion battery anode materials.
