

How to protect the battery in low current devices

What does a battery protection circuit do?

The battery protection circuit disconnects the battery from the load when a critical condition is observed, such as short circuit, undercharge, overcharge or overheating. Additionally, the battery protection circuit manages current rushing into and out of the battery, such as during pre-charge or hotswap turn on.

Can a protection device trip a battery?

The selected protection device must trip in case of a fault in less than 100 ms. In case the fault current provided by the battery does not allow for the finding of protection devices, such as a Circuit Breaker or fuse, that meets the derating criteria stated in point B, it is hence possible to increase the multiplier up to 0.7.

How a battery protection device should be sized?

A protection device must be sized properly so that the energy flowing from the batteries during the failure will not cause damage to the batteries or other components along the short circuit path. The protection must clear the fault in less than 100 milliseconds. The impedance of the line is mainly resistance and inductance.

Can Li-ion batteries go out of control without protection?

Although Li-ion batteries are convenient thanks to their rechargeability, they could go out of control without proper protection. To support designing Li-ion-battery-powered systems of high safety, we provide Li-ion battery protection ICs equipped with variety of optional protection functions.

How to choose a battery protection IC?

Considerations in choosing battery protection ICs Two important parameters in battery ICs are overvoltage threshold and undervoltage threshold. These numbers are the voltage levels at their limit; the IC will cut the cell out of circuit if the cell is being overcharged or over-discharged.

What are the technical parameters of lithium battery protection boards?

Prevent the battery from being damaged by excessive current. Important technical parameters of lithium battery protection boards include overcharge protection, over-discharge protection, over-current protection, short-circuit protection, temperature protection, internal resistance, power consumption, etc.

Under normal conditions, it has high impedance and very low leakage current, effectively acting like an open circuit. When the voltage exceeds its threshold, the avalanche effect in the semiconductor activates, causing the p-n junction to conduct and create a low-impedance path that diverts excessive current away from the protected device.
