

What is the construction of a capacitor?

The construction of capacitor is very simple. A capacitor is made of two electrically conductive plates placed close to each other, but they do not touch each other. These conductive plates are normally made of materials such as aluminum, brass, or copper. The conductive plates of a capacitor are separated by a small distance.

How does a capacitor work?

Basically, a capacitor consists of two parallel conductive plates separated by insulating material. Due to this insulation between the conductive plates, the charge/current cannot flow between the plates and is retained at the plates.

What determines the capacitance of a capacitor?

The capacitance of the capacitor mainly depends upon the surface area of each plate, the distance between two plates and the permittivity of the material between the two plates. Basic circuits of a capacitor mainly include capacitors connected in series and capacitors connected in parallel.

What is a capacitor in a circuit diagram?

Each plate is connected to an external terminal, enabling the capacitor to be integrated into an electrical circuit. The standard symbol used to represent a capacitor in circuit diagrams consists of two parallel lines representing the plates of the capacitor, separated by a gap to signify the dielectric material.

Is a capacitor a conductive material?

This non-conductive material is called dielectric. The two conductive plates of the capacitor are good conductors of electricity. Therefore, they can easily pass the electric current through them. The conductive plates of the capacitor also hold the electric charge.

How does a capacitor behave like a battery?

And a capacitor behaves like a battery. Their size varies from a small bead type used in electronic circuitry and large ones used for power factor improvement in power circuitry. Basically, a capacitor consists of two parallel conductive plates separated by insulating material.
